Ref No 6021 (v8)

Hand Arm Vibration Syndrome (HAVS)

Introduction

Hand Arm Vibration Syndrome (HAVS) will often affect the people who regularly use high vibration equipment such as hand tools. One of the most common types of HAVS is Vibration White Finger. The vibration of the tool or any material being worked is transmitted to the hands where it could cause a range of problems such as bone and joint disorders, damage to the nerves and muscles, but most characteristically, whitening of the fingers as a result of disruption to the blood flow.

The early symptoms of HAVS are often only the whitening of the finger tips but the area affected will gradually increase and extend down the finger, even after exposure to the vibration. The attacks can often be set off by cold. During the attack, the fingers will turn white and may be numb or a tingling sensation may be felt. They can last up to half an hour and be very painful, especially as the blood returns to the fingers and the colour turns back to red.

Identifying HAVS Risks

Many common tools and processes produce high levels of vibration. Pneumatic drills or jackhammers, grinders, riveting and chipping hammers are all good examples.

The degree of risk will depend on many factors. The amount of vibration, how long the tools are used for, the working posture and how cold it is will all make a difference. Consult with employees, safety representatives and supervisors on the subject and what measures need to be put in place.

Legal Requirements

Regulations dealing with vibration risks were introduced in 2005.

The Control of Vibration at Work Regulations require employers to:

- Assess the risks from vibration to employees and decide if the levels are likely to exceed:
  - The daily exposure action value (EAV) or
  - The daily exposure limit values (ELV)
- If above the EAV:
  - To eliminate or reduce the risks to as low as reasonably practical
  - Provide health surveillance
- If above the ELV:
  - Reduce the exposure to below ELV
- Provide information and training on the risks to exposed employees and the necessary steps to control them

Exposure Action Values (EAV) and Exposure Limit Values (ELV)

The EAV is a daily amount of vibration above which employers are required to take action to control exposure. The EAV for hand-arm vibration is a daily exposure of 2.5 m/s² (A)8 (a value averaged over an 8-hour exposure period).

The ELV is the maximum level of exposure permitted by the regulations. The ELV is a daily exposure of 5 m/s² A(8). Exposure levels must be reduced to below this level.

Risk Assessments

The purpose of the assessment is to determine whether or not the EAV or ELV are exceeded, and if so to determine what needs to be done to reduce the risks.

- Make a list of equipment that may cause vibration
- Collect information about the equipment on vibration risks (from manufacturers)
- Identify the employees who use the equipment
- Note for how long the employees are actually in contact with the machinery when vibrating. (this “trigger time” may only be a few minutes in several hours of working time)
Key Action Steps

- Undertake a risk assessment to identify if the EAV or ELV are exceeded.
- Consider measures required to reduce the risks from Hand Arm Vibration.
- Decide upon any health surveillance.
- Implement and maintain a stringent policy for purchasing new power tools.

Health Surveillance

If there are any employees who are exposed to vibration levels above the EAV or are otherwise thought to be at risk, then their health should be regularly checked to identify any employees who may at special risk (e.g. because of any existing medical conditions); detect any early signs of vibration-related disease; check the effectiveness of controls. Basic health surveillance consists of seeking information about early symptoms, possibly using a questionnaire. As an alternative, health surveillance can be provided by an occupation health service provider.

Training and Information

Employees should be provided with information on-

- The effects of hand-arm vibration
- Sources of hand-arm vibration
- The findings of the risk assessment
- The symptoms and how to report them
- Ways of reducing the risks

INDG 296 (see references) can help in providing this information and training.
